Remarks:

Divisional application 97113748.4 filed on 08/08/97.

Description

The present invention relates to polypeptides encoded by the human polymorphic epithelial mucin gene and to the use of the polypeptides in the therapeutic treatment of cancer and in *in vitro* diagnosis.

Normal and malignant human mammary epithelial cells express high molecular weight glycoproteins (gps) which are extensively glycosylated and very antigenic. As a result, many of the monoclonal antibodies (MAbs) selected for reactivity with human breast cancer and other carcinomas are found to react with molecules which are produced in abundance by the fully differentiated human mammary tissue and are found in the milk fat globule (MFG) and in milk. However, the level of expression of a particular antigenic determinant may be different in the gps produced by the normal differentiated cell and in the similar molecules produced by breast cancers. This means that some antibodies can show a certain specificity for reacting with tumour gps.

The molecules bearing the epitopes recognised by these antibodies are complex and have been difficult to analyse, both because they are large and heavily glycosylated (>250,000 daltons) and because of the complex pattern of expression. Two of the MAbs, HMFG-1 and -2, react with a component in human milk which appears to be greater than 400,000 daltons, whereas the molecules found in sera and tumours are smaller, although the dominant components are still greater than 200,000 daltons on immunoblots. The large glycoprotein produced by the differentiated mammary epithelial cells found in human milk or in the milk fat globule has been purified and shown to have some of the characteristics of the mucins. This component contains a large amount of carbohydrate joined in O-linkage to serine and threonine residues via the linkage sugar N-acetyl-galactosamine. Moreover, the core protein contains high levels of serine, threonine and proline and low levels of aromatic and sulphur containing amino acids.

These mucin-like glycoproteins are also secreted by a number of other normal epithelial cells. The monoclonal antibody HMFG-1 is highly reactive with the milk mucin and evidence suggests that the epitope recognised by this antibody is more abundant on the fully processed mucin, characteristic of normal differentiation.

In tumours, the molecular weight of the molecules carrying these antigenic determinants differs among individual tumours and, in the case of the components recognised by the HMFG-2 antibody, can range from 80-400K daltons. Although it appears that the differences observed in the mobility of the high molecular weight bands are due to genetic polymorphism this probably does not explain variations in the size of the lower bands. It has been proposed that these may be the result of aberrant processing occurring in the tumour cell possibly within the glycosylation pathways.

For the majority of the monoclonal antibodies reacting with this group of molecules the exact nature of the antigenic epitopes remains unclear but circumstantial evidence has suggested that carbohydrate may at least be partly involved in many of the epitopes. Moreover, from previously available data it was not known whether the mucin found in the normal differentiated cells, and that observed in the tumours, contain the same core protein, or just carry common carbohydrate determinants.

Mucin has now been isolated from human milk by affinity chromatography enabling identification of the core protein and the gene encoding the protein. This has been found to be a highly polymorphic gene defined by the peanut urinary mucin (PUM) locus [see Swallow *et al.*, *Disease Markers*, 4, 247, (1986) and *Nature*, 327, 82-84 (1987)]. The gene product, which is hereafter referred to as human polymorphic epithelial mucin or HPEM, has been detected in breast tumours and other carcinomas as well as in some normal epithelial tissues.

Rittenhouse *et al.* (Laboratory Medicine, 16(9), 556-560 (1985)) review the field of mucin-type glycoproteins as tumour markers and argue that the distinction between normal and tumour mucins is associated with different patterns of glycosylation.

Ormerod *et al.* (Br. J. Cancer (1983), 48, 533-541) have partially purified epithelial membrane antigen (EMA), a soluble component of human milk, and have partially deglycosylated this by chemical means.

Sekine *et al.* (J. Immunol. 135, 3610-3615 (1985)) describes the murine monoclonal antibody DF3 and characterisation of its human breast carcinoma-derived antigen as a mucin-like glycoprotein having several sialyl oligonucleotides on a peptide backbone, based on studies including enzyme and chemical digestions of the antigen.

Gendler *et al.* (J. Cell Biology US (1986), 103(5), part 2 abstract 93) discusses the stripping of glycosylation from human milk mucin, antibodies raised against the core protein and their use in probing a cDNA expression library.

It has now been found that the HPEM core protein has epitopes which also appear in the aberrantly processed gps produced by adenocarcinoma cells. Certain of these epitopes are not exposed in the fully processed mucin glycoprotein produced by the lactating mammary gland.

Antibodies have been made against the HPEM core protein that react with the core protein, especially as expressed by colon, lung, ovary and particularly breast carcinomas, but have reduced or no reaction with the corresponding fully processed HPEM, particularly as produced by the normal lactating human mammary gland.

Such antibodies have no significant reaction with the mucin glycoproteins produced by pregnant or lactating mammary epithelial tissues but react with the mucin proteins expressed by mammary epithelial adenocarcinoma cells. These antibodies show a much reduced reaction with benign breast tumours and are therefore useful in the diagnosis and localisation of breast cancer as well as in therapeutic methods.

The antibodies may be used for other purposes including screening cell cultures for the polypeptide expression product of the human mammary epithelial mucin gene, or fragments thereof, particularly the nascent expression product. In this case the antibodies may conveniently be polyclonal or monoclonal antibodies.

These antibodies may be produced by inoculation of suitable animals with HPEM core protein or a fragment thereof such as the peptides described below. Monoclonal antibodies are produced by the method of Kohler & Milstein (Nature 256, 495-497/1975) by immortalising spleen cells from an animal inoculated with the mucin core protein or a fragment thereof, usually by fusion with an immortal cell line (preferably a myeloma cell line), of the same or a different species as the inoculated animal, followed by the appropriate cloning and screening steps.

One such antibody is the monoclonal antibody designated SM3 against the HPEM core protein. The hybridoma cell line which secretes the antibody SM3 has been designated HSM3. Samples of HSM3 have been deposited with ECACC on 7th January 1987 under accession number 87010701.

Using such antibodies it has been possible to screen a phage library constructed from mRNA isolated from a human breast cancer cell line to identify sequences coding for portions of the mucin core protein. Complementary DNA sequences have been constructed and from these it has surprisingly been found that the gene encoding the core protein contains multiple tandem repeats of a 60 base sequence leading to considerable polymorphism sufficiently extensive that cDNA fragments corresponding to the repeat sequence would be useful for fingerprinting DNA.

A double tandem repeat has the following sequence:

```

5'
GTC ACC TCG GCC CCG GAC ACC AGG CCG GCC-
*
CCG GGC TCC ACC GCC CCC CCA GCC CAC GGT-
GTC ACC TCG GCC CCG GAC ACC AGG CCG GCC-
*
CCG GGC TCC ACC GCC CCC CCA GCC CAC GGT
3'

```

When the existence of a tandem repeat sequence was first identified it was believed that the sequence originally defined in British Patent Application No. 8700269 consisted of 59 base pairs corresponding with the sequence indicated above except for the lack of the base indicated with ***.

The invention provides a polypeptide recognisable by the monoclonal antibody SM3 secreted by the hybridoma HSM3 (ECACC 87010701) comprising at least 5 consecutive amino acid residues in a sequence encoded by the DNA tandem repeat sequence of mRNA corresponding to the human polymorphic epithelial mucin core protein gene, which mRNA is obtainable from the human cancer cell line MCF-7 for use in a method of therapy practised on the human or animal body. The invention also provides the use of polypeptides as defined above in the production of a medicament for use as an immunogen in a method of cancer therapy practised on the human or animal body and the use of such polypeptides in *in vitro* diagnosis.

Polypeptides for use according to the invention are selected from any of those having 5 or more amino acid residues represented by the following amino acid sequence

```

Val Thr Ser Ala Pro Asp Thr Arg Pro Ala Pro Gly Ser Thr
Ala Pro Pro Ala His Gly*Val Thr Ser Ala Pro Asp Thr Arg
Pro Ala Pro Gly Ser Thr Ala Pro Pro Ala His Gly
("*" marks the start of the repeat in the peptide).

```

Polypeptides for use according to the invention may have a sequence corresponding with any portion of the 40 residue sequence above and may include the start point of the repeat sequence.

Other polypeptides for use according to the invention include three or more repeats of the 20 amino acid repeat sequence. Such polypeptides may include minor variations by way of substitution of individual amino acid residues.

The invention further provides polypeptides as defined above modified by addition of N-acetyl galactosamine (a linkage sugar) on serine and/or threonine residues and by addition of oligosaccharide moieties to that or via other linkage sugars and/or fragments linked to carrier proteins such as keyhole limpet haemocyanin, albumen or thyroglobulin.

Preferably the polypeptide comprises at least 10 amino acid residues of the sequence above, more preferably 20 residues. The polypeptide may comprise the full sequence above. Such polypeptides may further comprise additional amino acid residues, preferably conforming to the amino acid sequence of HPEM core protein.

The polypeptides for use according to the invention encoded by the tandem repeat may be produced by culturing appropriate cells transformed with a vector. A nucleic acid fragment encoding the polypeptide together with any necessary or desirable flanking sequences (for instance with further coding or non-coding nucleic acid sequences including regulatory and promoter sequences, marker sequences and splicing or ligating sites) is inserted, in an appropriate open reading frame register, into a suitable vector such as a plasmid or a viral genome (for instance vaccinia virus genome) and is then expressed as a polypeptide product by conventional techniques. The polypeptide is then harvested and used as an immunogen to induce active immunity against the mucin core protein. Alternatively the vector, particularly in the form of a virus, may be directly inoculated into a human or animal to be immunised. The vector then directs expression of the polypeptide *in vivo* and this in turn serves as an immunogen to induce active immunity against the mucin core protein.

The HPEM core protein is encoded by the PUM gene and may be produced by recombinant DNA techniques and expressed without glycosylation in human or non-human cells. Alternatively it may be obtained by stripping carbohydrate from native human mucin glycoprotein which itself may be produced by isolation from samples of human tissue or body fluids or by expression and full processing in a human cell line. The HPEM core protein may be used immunogen in active immunisation of humans.

The invention will now be illustrated by the following Examples and with reference to the figures of the accompanying drawings in which

Figure Legends

Figure 1: Purification of the milk mucin by immunoaffinity chromatography using the antibody HMFG-1. Milks from several individuals were combined and absorbed to a HMFG-1-Sepharose column as described in methods. The material eluting at low pH was iodinated and subjected to PAGE electrophoresis and autoradiography (track 1). The iodinated material was precipitated using the Protein A method with antibodies HMFG-1 (track 5), HMFG-2 (track 2), ST254 (track 3) and RPMI + 20% FCS (track 4).

Figure 2: Comparison of the ^{125}I labelled purified milk mucin with immunoblot of human skimmed milk. A, human skimmed milk was subjected to SDS polyacrylamide electrophoresis, transferred to nitrocellulose paper, the blot probed with the monoclonal antibody HMPG-1 and binding detected using an ELISA method. B, after purification on an HMPG-1 affinity column followed by G75 Sephadex chromatography the milk mucin was iodinated by the Bolton and Hunter method and subjected to SDS polyacrylamide electrophoresis and autoradiography.

Figure 3: Autoradiography of the iodinated milk mucin after treatment with hydrogen fluoride. The purified milk mucin was treated with HF for 3 hours at room temperature (track 1) or 1 hour at 4°C (track 2) and the resulting preparations were then iodinated and run on SDS polyacrylamide gels.

Figure 4: Reactivity of the intact, partially stripped or extensively stripped milk mucin with iodinated lectins. The purified intact milk mucin (track 1), the mucin treated with HF for 1 hour at 4°C (track 2) and the mucin treated for 3 hours at room temperature (track 3) were subjected to SDS polyacrylamide electrophoresis and then transferred to nitrocellulose paper. The paper was then probed with ^{125}I PNA (peanut agglutinin), ^{125}I WGA (wheat germ agglutinin), or ^{125}I HPA (Helix pomatia agglutinin).

Figure 5: Immunoprecipitation and immunoblots of the partially and extensively stripped mucin. A, the ^{125}I extensively stripped mucin was immunoprecipitated with SM-3 (track 3), HMFG-2 (track 2) or NS2 medium as a control (track 1) by the protein A plate method (see Materials and methods). B, the partially stripped mucin (track 1) or extensively stripped mucin (track 2) was run on SDS polyacrylamide gels and transferred to nitrocellulose paper. The blot was then reacted with a cocktail of SM-3 and SM-4 monoclonal antibodies and the binding detected using an ELISA method.

Figure 6: Reactivity of monoclonal antibodies SM-3 and HMFG-2 with methacarn fixed breast tissue and tumour sections using an indirect immunoperoxidase staining method. Infiltrating ductal carcinoma showing strong reactivity with both SM-3 (A) and HMPG-2 (B). Fibroadenoma showing no reactivity with SM-3 (C) and strong heterogeneous

staining of the epithelium with HMFG-2 (D). Papilloma showing very weak reactivity with SM-3 (E) and strong positivity with HMPG-2 (F). Both normal resting breast (G) and lactating breast (I) were negative when stained with SM-3, whereas both tissues stained positively with HMPG-2 with lactating breast (J) much stronger than normal resting breast (H).

Figure 7. Periodic acid-silver stained milk mucin after antibody affinity column and gel filtration column. Milk mucin was purified on an HMFG-1 antibody affinity column (lane 1) followed by passage through a G75 Sephadex column. (lane 2), subjected to NaDodSO₄/polyacrylamide gel electrophoresis, and silver stained following treatment of gels with 0.2% periodic acid.

Figure 8. Silver stain of partially and totally stripped core protein from milk mucin. The purified milk mucin was deglycosylated by treatment with anhydrous hydrogen fluoride for 1 hr at 0°C (lane 1) and 3 hr at room temperature (lane 2), separated by electrophoresis through a NaDodSO₄/polyacrylamide gel (10%) and silver stained.

Figure 9. Immunoprecipitation with Mabs of *in vitro* translated protein products from MCF-7 poly(A)⁺ RNA. Poly (A)⁺ RNA from MCF-7 cells was translated in a rabbit reticulocyte lysate system (Amersham) in the presence of [³⁵S] methionine (1000 Ci/mole; 1Ci = 37 GBq) following the manufacturer's conditions. Samples containing 5 x 10⁴ acid precipitable cpm were precipitated with MAb SM-4 (lane a), SM-3 (lane b), HMFG-2 (lane c), HMFG-1 (lane d) and an irrelevant MAb to interferon (lane e, 24), separated on a NaDodSO₄/polyacrylamide gel (10%), impregnated with Amplify and exposed to XAR-5 film at -70°C for 20 days.

Figure 10. Immunoblot analysis of fusion proteins from the λmuc clones. The phage clones λMUC 3,4,6,7,8,9 and 10 were used to lysogenize bacterial strain Y 1089. Lysogens were grown at 32°C, shifted to 42°C, and then induced with IPTG. Lysogen proteins were fractionated by electrophoresis through a NaDodSO₄/polyacrylamide gel (7.5%), transferred to nitrocellulose, and reached with HMFG-2. The binding was detected with an ELISA method using 4-chloro-1-naphthol as the substrate. The numbers are those of the λ clones.

Figure 11. Hybridization of pMUC10 to cDNA inserts of pMUC clones. DNA from the plasmid clones was digested with restriction enzyme EcoRI to excise the cDNA inserts, separated by electrophoresis on 1.4% agarose and transferred to Biodyne nylon membrane. The filter was hybridized using standard conditions (34) to the insert from pMUC10 which was labelled with [α-³²P]dCTP by the method of random priming (41). Lanes: plasmid clones 3,4,6,7,8,9,10.

Figure 12. RNA blot hybridization analysis of mammary breast mucin mRNA. 10 μg of total RNA from human breast cancer cells MCF-7 (lane 1) and T47D (lane 2), normal human mammary epithelial cells HuME (lane 3), human embryonic fibroblasts ICRF 23 (lane 4), Daudi cells (lane 5) and carcinosarcoma HS578T cells (lane 6) were separated in a 1.3% agarose/glyoxal gel, blotted on to nitrocellulose and hybridized to the pMUC10 EcoRI insert which was labelled with [α-³²P]dCTP by the method of random priming (41). The size markers were 28S (5.4 kb) and 18S (2.1 kb) rRNAs.

Figure 13. Polymorphic human DNA fragments detected by hybridization with pMUC10 probe. Genomic DNA samples prepared from the white blood cells from ten individuals (six unrelated) and from three cell lines were digested to completion with HinfI and EcoRI, fractionated by electrophoresis through 0.7% and 0.6% agarose, respectively, and transferred to Biodyne nylon membranes. The filter was hybridized to the pMUC10 DNA insert which was labelled with [α-³²P]dCTP by the method of random priming (41). X-ray film was exposed for 1 day at -70°C with intensifying screens. Lanes 1-4 father, two daughters and mother, lanes 5-10 unrelated individuals, lane 11 is MCF-7, lane 12 is ZR75-1, lane 13 is ICRF-23. The DNA samples exhibit a wide distribution of sizes. Numbers indicate length of DNA in kb. The apparent bands at 23Kb are in lanes 12 and 13 are artefacts introduced in autoradiography.

Example 1

Purification of the milk mucin

The milk mucin was purified from human skimmed milk by passage through an HMFG-1 affinity column followed by size exclusion chromatography. The HMFG-1 monoclonal antibody was purified from tissue culture supernatant using a protein A column (1). The purified antibody was coupled to cyanogen bromide activated sepharose (Pharmacia) as described in the manufacturer's instructions. Human skimmed milk was passed in batches of 100 ml through the antibody column followed by extensive washing with PBS. Bound antigen was eluted from the column using 0.1 M glycine pH 2.5 and the fractions registering an optical density at 280nm were pooled, dialysed against 0.25 M acetic acid and lyophilized. Batches of about 20 mgs were dissolved in 0.25 M acetic acid and passed through a G75 Sephadex column (1 x 100 cm) which had been previously equilibrated with acetic acid. The column was washed with 0.25 M acetic acid and 1ml fractions collected. The peak fractions which were eluted in the void volume were pooled, lyophilized and the dry powder stored at 4°C. Amino acid analysis was performed using a Beckman 6300 amino acid analyser.

Deglycosylation of the milk mucin

To remove the O-linked carbohydrate from the milk mucin the molecule was treated with anhydrous hydrogen

fluoride as described by Mort and Lamport (21), for either 1 hour at 4°C which produced a partially stripped preparation, or 3 hours at room temperature which produced the extensively stripped mucin.

Iodination of the milk mucin

Iodinations of the purified mucin, the partially or extensively stripped mucin were carried out using the Bolton and Hunter method (51). Briefly, the mucin, 2.5 µg in 20 µl 0.1M borate buffer pH 8.5, was added to the dried Bolton and Hunter reagent (1 mCi, Amersham International plc) and incubated at room temperature for 15 minutes. The reaction was stopped by the addition of 0.5 ml of 0.2M glycine in borate buffer and after a further 15 minutes incubation, free Bolton and Hunter reagent was removed by passage through a G25 Sephadex column (PD10 columns, Pharmacia) previously equilibrated in PBS.

Iodination of Lectins

Wheat germ agglutinin (WGA), peanut agglutinin (PNA) (Vector Labs) and Helix pomatia agglutinin (HPA) (Boehringer) were iodinated as described by Karlsson et al. (52) using the chloramine T method.

Polyacrylamide gels and Western blots

Polyacrylamide gel electrophoresis and immunoblotting was performed as described previously (1). Briefly, samples were run on 5-15% polyacrylamide gels and then electrophoretically transferred to nitrocellulose paper (Schleicher and Schuell) at 50 volts overnight at 4°C (36). In the immunoblotting experiments the paper was reacted with monoclonal antibodies and binding detected with an ELISA method using 4-chloro-1-naphthol as the substrate. For lectin binding studies the Western blots were reacted with the iodinated lectins as described by Swallow et al. (48).

Production of monoclonal antibodies

A female BALB/c mouse was immunized with 5 µg of the partially stripped milk mucin in Freund's complete adjuvant and 3 months later boosted with a further 5 µg of the same preparation in Freund's incomplete adjuvant. After a further 20 days, 5 µg of the mucin extensively stripped of its carbohydrate was given intravenously in saline solution. The spleen was removed 4 days later, and fused with the NS2 mouse myeloma cell line (53).

Screening of hybridoma supernatant and immunoprecipitations

The screening assay was a modification of that described by Melero and Gonzalez-Rodriguez (54). Multiwell plates were coated with 50 µl of 0.1 mg/ml protein A (Pharmacia Fine Chemicals) in PBS and allowed to dry overnight at 37°C. The plates were blocked with 5% BSA for 1 hour at 37°C followed by the addition of 50 µl of rabbit anti-mouse immunoglobulin (DAKO, diluted 1:10 in PBS/BSA = PBS/BSA). After incubating for 2 hours at 37°C the plates were washed twice with PBS containing 1% BSA and 50 µl of hybridoma supernatant added. The plates were incubated overnight at 4°C, washed twice with PBS/BSA and 50 µl of iodinated partially stripped mucin containing 100,000 cpm added to each well. The plates were then incubated at room temperature for 4 hours, washed 4 times with PBS/BSA and the individual wells counted in a gamma counter. For immunoprecipitation experiments 50 µl of SDS sample buffer containing dithiothreitol was added to each of the wells which were then boiled for 3 minutes and the buffer loaded onto 5-15% polyacrylamide gradient gels.

Staining of tissue sections

Tissues from primary mammary carcinomas, benign breast biopsies, normal breast, and pregnant lactating breast tissue were fixed in methacarn (methanol chloroform and acetic acid 60:30:10) and embedded into paraffin wax. Sections were stained with the antibodies using the indirect peroxidase anti peroxidase method as previously described (47).

Results

Purification of the milk mucin

The milk mucin was purified from human skimmed milk on an HMFG-1 antibody affinity column. Iodination of the eluted material revealed the presence of a large molecular weight component and a 68KD band. Precipitation of the

affinity purified material with antibodies HMFG-1 and HMFG-2 (tracks 2 and 5) followed by gel electrophoresis showed that both the high molecular weight components and the 68KD component were precipitated by both antibodies (less effectively by HMFG-2). Since the 68KD component was also precipitated by two unrelated antibodies (figure 1, tracks 3 and 4) and this component was not evident on an immunoblot of the purified material reacted with HMFG-1 (figure 2A), the 68K component was removed by molecular sieve chromatography on a G75 column. The final purified product showed a major high molecular weight band, with only a trace of the 68K component and a minor contaminant around 14K (figure 2B).

A high molecular weight glycoprotein (PAS-O) containing more than 50% carbohydrate in O-linkage has been purified from the human milk fat globule by Shimizu and Yamauchi (8). To see whether this component was similar to the mucin isolated from milk by affinity chromatography on an HMFG-1 affinity column, the amino acid composition of the purified HMFG-1 reactive mucin was determined and compared to the amino acid composition of the purified PAS-O component. Table 1 shows that there is good correspondence between the two sets of data, indicating that the core proteins of PAS-O and the mucin purified here are the same.

Isolation of the core protein of the milk mucin

As there are no enzymes easily available that are efficient at removing O-linked sugars, and β elimination often results in damage to the protein core, the oligosaccharides were removed by treatment of the mucin with anhydrous hydrogen fluoride. This treatment has been shown by Mort and Lampert (21) to be effective in removing sugars from pig submaxillary mucin without damaging the protein core. Amino acid analysis of the material produced after HF treatment of the milk mucin suggested that the protein core was also in this case undamaged, since the composition was the same as that seen in the intact mucin (Table 1).

Initially the milk mucin was exposed to HF for only 1 hour at 4°, but analysis of the product showed that there was only partial removal of the sugars with such treatment, and it was necessary to treat the mucin at room temperature for 3 hours to obtain a molecule which showed no lectin binding ability. Figure 3 shows an autoradiograph of the iodinated products after treatment for 1 hour at 4° (track 2) or 3 hours at RT (track 1). It can be seen from Figure 3 that the milder treatment results in a mixture of products made up of high molecular weight material which is slightly smaller than the intact mucin and a number of smaller bands. After longer exposure to HF at room temperature, the high molecular weight bands disappeared resulting in polypeptide bands of about 68KD and 72KD.

To test for the presence of sugars on the intact mucin and on the products produced after the two different HF treatments each preparation was subjected to acrylamide gel electrophoresis, transferred to nitrocellulose paper and reacted with ¹²⁵I-labelled lectins. The lectins used were peanut lectin (PNA) which reacts with galactose linked to N-acetyl galactosamine, wheat germ (WGA) reactive with N-acetyl glucosamine and Helix pomatia agglutinin (HPA) which reacts with the linkage sugar in O-linked glycosylation, N-acetylglactosamine. Figure 4 shows autoradiographs of the reacted blots, and it can be seen that while treatment with HF for 1 hr at 4° (track 2) alters the lectin reactivity of the mucin, carbohydrate is still present. Interestingly, however, there is a much lower level of binding of PNA to the high molecular weight material of the partially stripped mucin than is seen with the intact mucin (track 1). Moreover, this loss in PNA binding ability is accompanied by binding of the linkage sugar specific lectin HPA. This lectin shows no binding at all to the intact mucin, and the changed pattern of lectin binding after limited treatment with HF indicates that sugars masking the O-linked N-acetylglactosamine have been stripped off. The smaller component seen in both the intact mucin (track 1) and in the partially stripped preparation (track 2) is a glycoprotein which reacts with WGA, although not with PNA. This may correspond to the component of similar molecular weight (around 68K) seen after affinity chromatography of the mucin and may represent an intermediate precursor molecule.

Figure 4 shows clearly that the 68K and 72K components produced after extensive treatment with HF (3 hr at RT), show no reactivity with the lectins (track 3), including the N-acetylglactosamine specific lectin HPA. This observation constitutes strong evidence that the sugars have been removed from at least the majority of the molecules, and we will refer to this preparation as the extensively stripped mucin.

Generation of monoclonal antibodies to the milk mucin core protein

A fusion was carried out using the spleen of a mouse that had been immunized with two injections of the partially stripped milk mucin followed by a boost with the extensively stripped mucin. The clones were initially screened against the ¹²⁵I partially stripped material using protein A plates (see Methods). Four hybridomas were selected and cloned, and table 2 shows their spectrum of reactivity with the intact, partially and extensively stripped mucin. As can be seen from this table three of the hybridomas which were isolated showed a strong reaction with the partially and extensively stripped mucin and did not react with the intact mucin. There appeared to be good candidates for monoclonal antibodies to the protein core and two, SM-3 and SM-4, were selected to be characterised further.

It can also be seen from table 2 that the HMFG-1 and HMFG-2 antibodies reacted very strongly with the mucin

stripped of its carbohydrate. These two antibodies were, in fact, developed using the intact mucin (from the milk fat globule) as immunogen and, in the case of HMFG-2, growing mammary epithelial cells (14). Their reaction with the stripped mucin was unexpected, as circumstantial evidence had previously led to the belief that carbohydrate might form at least part of their antigenic epitopes.

Molecular Weight of molecules carrying antigenic determinants

The antibody SM-3 was shown to be of the IgG1 subclass, while the SM-4 antibody was found to be IgM. We therefore chose to use the SM-3 antibody in subsequent experiments since antibodies of the IgM class can present problems in some application. Immunoprecipitation of the extensively stripped material with SM-3 showed a reaction with the lectin unreactive 68K component (Figure 5A, track 3). The monoclonal antibody HMFG-2 can also be seen to immunoprecipitate the lectin-unreactive 68K component (track 2). The antibodies were reactive with antigen on immunoblots and Figure 5B shows the reaction of antibody SM-3 with the dominant 68K band of the extensively stripped mucin (track 2).

We have previously shown that the molecular weight of the components in breast cancer cells carrying determinants found on the milk mucin is lower than 400K and can vary from one tumour to another (1). Reaction of antibody SM-3 with Western blots of gel separated extracts of breast tumour cells shows that this antibody reacts with components of similar molecular weight to those reactive with antibody HMFG-2 (data not shown). Because the antibody SM-3 differs from the antibodies HMFG-1 and 2 in that it does not react with the intact mucin processed by the lactating gland and yet reacts with molecules processed by breast cancer cells, it was appropriate to examine the reaction of SM-3 with a range of breast cancers.

Reactivity of SM-3 with breast tissues and tumours

The antibody SM-3 reacted with paraffin embedded tissues provided these were fixed in methacarn (not formal saline). Using this method for preparation of tissue sections, the reaction of the antibody was compared to that of HMFG-2 on breast tissues and tumours with an indirect immunoperoxidase staining method. This analysis showed a dramatic difference in the staining pattern of SM-3 compared to that seen with HMFG-2. Thus, although a strong positive reaction was seen in 20/22 breast cancers stained with SM-3 (as compared to 22/22 stained with HMFG-2), normal resting breast, pregnant or lactating tissues and most benign lesions were largely unstained with SM-3 but were stained with HMFG-2. Some examples of staining patterns of breast tissues and tumours are illustrated in Figure 6.

Twenty-two primary carcinomas and fourteen benign lesions were examined and the reaction of SM-3 compared to the staining with HMFG-2 in each case. In the primary carcinomas, staining with SM-3 was heterogeneous but generally quite strong and always confined to tumour cells; connective tissue and stroma showed no reaction (see figures 6A,B). In the four fibroadenomas examined, staining of the epithelium with HMFG-2 was strong although heterogeneous. In comparison, staining with SM-3 was negative in one case and in the three others staining was confined to only one or two glandular elements. HMFG-2 showed strong positivity on the five papillomas and five cases of cystic disease studied while the staining observed with SM-3 was very much weaker and more heterogeneous (figures 6G, H). The papillomas as a group showed the strongest staining with SM-3, and it can be seen that the staining was membranous or extracellular.

In contrast to HMFG-1 and HMFG-2 which strongly stain lactating and pregnant breast, SM-3 was totally negative with three out of six cases of pregnant or lactating breast (see figure 6C and D). Two positive cases showed only very weak staining of an occasional cell and in the third, staining was confined to two areas of one lobule. Again, in contrast to HMFG-1 and HMFG-2 which do react with some terminal ductal lobular units of normal, resting breast (albeit weakly), SM-3 was totally negative on eight out of the thirteen cases tested and in the other five cases staining was extremely weak and often confined to one or two acini in the tissue section (see figure 6E and F). It should perhaps be noted that the intensity of staining with HMFG-2 seen with normal breast tissues and benign lesions fixed in methacarn was somewhat higher than that reported previously using formalin fixed material (50,47).

SM-3 was also shown to be negative on sections of normal liver, lung, thymus, sweat gland, epididymus, prostate, bladder, small intestine, large intestine, appendix, thyroid and skin. The antibody showed weak positive staining only with the distal tubules of the kidney, the occasional chief cell of the stomach, the occasional duct cell of the salivary gland and the sebaceous gland.

Discussion

Large molecular weight mucin molecules are expressed by many carcinomas and carry many of the tumour associated antigenic determinants recognised by monoclonal antibodies. These epitopes may also be expressed by some normal epithelium, and some monoclonal antibodies like HMFG-1 react particularly well with a mucin found in

normal human milk (1,17). As long as the study of the mucins is restricted to their detection with antibodies reactive with undefined epitopes, the knowledge of their structure, expression and processing will also be restricted. We have begun to investigate the structure and expression of the mammary mucin by isolating the core protein and developing antibodies which have allowed us to select partial cDNA clones for the gene coding for the core protein. This Example describes the production and characterization of these antibodies.

Treatment of the HMFG-1 affinity purified milk mucin with hydrogen fluoride resulted in the appearance of a dominant band of about 68K daltons and a minor species of about 72KD on SDS acrylamide gels. These bands showed no reactivity with lectins, including *Helix pomatia* agglutinin which is specific for N-acetyl galactosamine, the first sugar in O-linked glycosylation (55). It therefore seems probable that this 68K dalton polypeptide represents the core protein of the mucin. Supportive evidence for this comes from the observation that the antibodies described here, which are reactive with the stripped 68K component, can precipitate a molecule of this size from the *in vitro* translation products of mRNA isolated from breast cancer cells expressing the mucin.

As the milk mucin contains at least 50% carbohydrate (16), a protein core of only 68KD appears too small if the intact molecule has an observed molecular weight greater than 400KD. However, mucins can be composed of small subunits which aggregate and are held together by some form of non-covalent interactions, as yet not understood. For example, although the molecular weight of the ovine submaxillary mucin has been reported to be greater than 1×10^6 daltons (45), it has a protein core of only 650 amino acids with a molecular weight of 58,300 daltons (46).

An unexpected finding was that the antibodies HMFG-1 and HMFG-2 which react with the milk mucin, also show a positive reaction with the extensively stripped material which showed no lectin binding capability. Previous indirect evidence, including the resistance to fixation, boiling and reduction, the repetitive nature of their epitopes and the appearance of several bands on immunoblots, had led to the belief that carbohydrate present on the milk mucin was involved in these epitopes. This idea was reinforced by the observation that lectins could block the binding of HMFG-1 and 2 (1). While it is not possible to exclude the possibility that some sugars, undetected by the lectin binding experiments, remain on the extensively stripped mucin described here, this is unlikely to be the explanation for the reactivity of the antibodies HMFG-1 and 2. This can be said since both antibodies have recently been shown to react positively with β -galactosidase fusion proteins expressed by phage carrying DNA coding for the core protein of the mammary mucin. It appears therefore that at least part of each of the epitopes recognised by HMFG-1 and HMFG-2 contain amino acids but it must be assumed that some of these epitopes on the core protein are exposed, i.e. not masked in the fully glycosylated molecule. The HMFG-2 epitope is however less abundant on the milk mucin than the HMFG-1 epitope, while it is readily detectable on the mucin molecules expressed by tumours (1). These molecules have a smaller molecular weight and may be less heavily glycosylated or polymerized.

Here we have reported the development of new antibodies which are reactive with the protein core of the mucin and with the partially deglycosylated molecule, but which are unreactive with the fully processed mucin produced by the lactating mammary gland. One of these antibodies SM-3, which is an IgG1, has been studied in more detail. It has been shown to react with the mucin molecules which are produced by breast cancer cells and are recognised by many antibodies developed against the intact milk mucin. It should be emphasized however that the epitope recognised by SM-3 which is on the core protein and is exposed in the mucin as processed by tumour cells, is not exposed on the normally processed milk mucin. This feature offers the possibility of enhanced tumour specificity, and a pilot immunohistochemical study of breast tumours and tissues has shown that indeed the SM-3 antibody reacts strongly with the majority of primary breast cancers (91%) but shows little or no reaction with benign breast tumours, resting or lactating breast, and most normal tissues.

There are several implications of the work described here which may be important for both basic and clinical studies in breast cancer. The observation that parts of the core protein (detectable by antibodies) are exposed on the mucins as processed by breast cancer but masked on the mucin as processed by cells in normal breast and benign tumours implies that there is an alteration in the processing of the mucin in malignancy. A more detailed study of the processing of the mucin in normal and malignant cells may then give basic information for defining the malignant cell. Moreover, since the specificity of the reaction of the antibody SM-3 for tumours is better than that of antibodies developed against the intact mucin, this antibody may prove to be a more effective diagnostic tool for the detection of breast cancer cells in tissue sections, tissue fluids and cells. The reactive components are membrane associated as well as intracellular and *in vivo* localisation of tumours may also be possible.

Abbreviations

The abbreviations used are: HMFG, human milk fat globule; PBS, phosphate-buffered saline (153 mM NaCl, 3 mM KCl, 10 mM Na_2HPO_4 , 2 mM KM_2PO_4 pH 7.4); WGA, wheat germ agglutinin; PNA, peanut agglutinin; HPA, *Helix pomatia* agglutinin; BSA, bovine serum albumin; SDS, sodium dodecyl sulfate.

Example 2

Purification and deglycosylation of human milk mucin was conducted as in Example 1 mucin was purified on an HMFG-1 antibody.

The striped mucin preparations were separated by electrophoresis through NaDodSO₄/polyacrylamide gels (10%) and silver stained by two methods, one of which can be used to stain highly glycosylated proteins (22,23).

Preparation of polyclonal rabbit antiserum to stripped core protein

One New Zealand White rabbit was immunized with 100 µg of the partially stripped core protein in complete Freund's adjuvant (Gibco). Booster injections of 500 µg of the totally stripped core protein were administered in incomplete Freund's adjuvant (Gibco) 3 and 4 weeks after the initial injection and the rabbit was bled one week later. Ten microliters of immune serum (75 µg/ml protein) precipitated 200 ng of fully stripped core protein in a Protein A assay (24) and detected it on immunoblots. The immunoglobulin fractions of rabbit preimmune and rabbit anti-mucin core protein were prepared by adding ammonium sulfate to 50% saturation. The resulting pellet was resuspended in one-half the original serum volume of PBS and dialyzed against the same buffer. After dialysis, only residual precipitate was removed by centrifugation. Immunoglobulin fractions were stored in aliquots at -20°C.

Description of MAbs used

In addition to the polyclonal antiserum used for initial screening, a cocktail of two MAbs, SM-3 and SM-4 (see Example 1) which recognise the mucin core protein (20) and HMFG-1 and HMFG-2 (1,14) were used to screen the purified plaques, the β-galactosidase fusion proteins and immunoprecipitations from *in vitro* translated proteins*. Other MAbs used were a monoclonal anti-β-galactosidase antibody (25) which was a gift from H. Durbin (ICRF, London), an anti-interferon antibody, ST254 (24), LE61, a keratin antibody (26) and M18 which recognizes a carbohydrate structure on the milk mucin (27).

In Vitro translation of proteins

RNA was isolated from the human breast cancer cell line MCF-7 using the guanidium isothiocyanate method of Chirgwin et al. (28) and poly(A)⁺ RNA was purified by chromatography using oligo (dT)-cellulose (New England Bio Labs). The poly(A)⁺ RNA was translated in a reticulocyte lysate system (Amersham) in the presence of [³⁵S] methionine (1000 Ci/mole; 1 Ci = 37 GBq, Amersham). Samples containing 5 x 10⁴ acid insoluble cpm were precipitated in a protein A assay (24) using MAbs SM-3, SM-4, HMFG-1, HMFG-2 and a control antibody to human interferon. The antibody-selected proteins were then separated on a 10% NaDodSO₄/polyacrylamide gel, impregnated with Amplify (Amersham) and exposed to XAR-5 film (Kodak) at -70°C.

Antibody screening of λgt11 library and protein blotting

The λgt11 library used in this study was constructed from mRNA isolated from the human breast cancer cell line MCF-7 and was generously provided by Philippe Walter and Pierre Chambon (Strasbourg, France). The poly (A)⁺ RNA used for the preparation of the randomly primed library was prepared from mRNA that sedimented faster than 28S rRNA and was enriched in estrogen receptor (29). The library was made essentially as described by Huynh et al. and Young and Davis (30-32) and contained approximately 1 x 10⁶ recombinants per µg of RNA. Between 85% and 95% of the plaques contained inserts.

The phage library was plated onto bacterial strain Y1090 and grown for 3 hr at 42°C. After isopropyl β-D-thiogalactoside (IPTG) induction and 3 hr of growth at 37°C, filters were prepared from each plate and screened with anti-mucin core protein antibody by the method of Young and Davis (32). The first antibody used in screening was the rabbit antiserum raised against the stripped core protein prepared as described above. Prior to use in screening, the antiserum was diluted 1:200 in PBS containing 1% bovine serum albumin (PBS/BSA). Preabsorption with Y1090 bacterial lysate was not found to be necessary. The nitrocellulose filters (Schleicher and Schuell) were blocked by incubation in PBS containing 5% BSA for 1 hr at room temperature with gentle agitation. The filters were incubated at room temperature overnight with a 1:200 dilution of antiserum in heat sealed plastic bags. The filters were washed 5 x 5 min in PBS/BSA, and bound antibody was detected by using horseradish peroxidase-conjugated sheep anti-rabbit antiserum (Dako) diluted 1:500 with PBS/BSA and incubated for 2 hr with the filters. The filters were washed 5 x 5 min in PBS/BSA and 1 x 10 min in PBS before color detection using 4-chloro-1-naphthol (1). Immunoreactive bacteriophage were picked

*The MAbs SM-3 and SM-4 (SM refers to stripped mucin) show strong reactivity with the partially and fully stripped core protein but no reactivity with the fully glycosylated mucin (20).

and purified through two additional rounds of screening. Subsequently, bacteriophage inserts were subcloned into the EcoRI sites of pUC8 (33) producing the plasmid used most extensively, pMUC 10. The plasmids were maintained in DH1 cells.

To examine the β -galactoridase-cDNA fusion proteins for immunoreactivity, cell lysates were derived. Lysogens were prepared as described in Young and Davis (34). Cells were pelleted, suspended in Laemmli sample buffer (35) and separated by electrophoresis through NaDodSO₄/polyacrylamide gels (10%) and transferred onto nitrocellulose filters as described (1,36). The filters were treated as above for antibody screening.

Northern Analysis

RNA was isolated from tissue culture cells and frozen tissues by the guanidinium isothiocyanate method of Chirgwin et al. (28). Total RNA (10 μ g per lane) was denatured by heating at 55°C for 1 hr in deionized glyoxal and fractionated by electrophoresis through a 1.3% glyoxal gel (38). The RNA was transferred to nitrocellulose (Schleicher and Schuell), prehybridized and hybridized as described by Thomas (34). Filters were washed down to 0.1X SSC with 0.1% SDS at 65°C and exposed to XAR-5 film (Kodak) at -70°C with intensifying screens.

Southern analysis

High molecular weight genomic DNA was prepared from white blood cells and cell lines (39,40). These genomic DNAs (10 μ g) were cleaved with restriction enzymes following the manufacturer's recommended conditions and fractionated through 0.6% and 0.7% agarose gels. Cloned plasmid DNA was cleaved and fractionated on 1.3% agarose. The gels were denatured, neutralized and transferred to nylon membranes (Biodyne) according to the manufacturer's instructions. The EcoRI insert from pMUC10 was separated on a 1% low melting point agarose (Biorad) gel and labelled with [α -³²P]dCTP by the method of random priming (41) and hybridized to filters at 42°C. Filters were washed down to 0.1X SSC with 0.1% SDS at 55°C and exposed to XAR-5 film (Kodak) at -70°C with intensifying screens.

Results

Purification and deglycosylation of mucin glycoprotein

Mucin glycoprotein reactive with the monoclonal antibody HMFG-1 was prepared from pooled human breast milk by using an HMFG-1 antibody affinity column, followed by molecular sieve chromatography on Sephadex G-75 in order to remove lower molecular weight components (Figure 7, lane 1). In order to demonstrate the homogeneity of the purified molecule, amino acid analyses of four separate preparations were performed and revealed a fairly consistent composition with serine, threonine, proline, alanine and glycine accounting for 58% of the amino acids. Periodic acid silver stained gels revealed a diffuse band of greater than 400,000 daltons visible only when the gel was treated with periodic acid before the silver stain (Fig. 7, lane 2). No other lower molecular weight bands were visualized on the gel using the silver stain without prior treatment with periodic acid.

The purified material was subjected to treatment with hydrogen fluoride to remove the O-linked sugars that are characteristic of mucin glycoproteins. Two different reaction conditions were used which resulted in a partially deglycosylated core protein (treated at 0°C for 1 hr) and a fully deglycosylated core protein (treated at room temperature for 3 hr) as determined by iodinated lectin binding following separation by gel electrophoresis and transfer to nitrocellulose paper (20). The partially deglycosylated core protein was reactive with wheat germ agglutinin, peanut agglutinin and helix pommatia lectin (which recognizes the linkage sugar N-acetylgalactosamine) whereas the fully stripped protein showed no reactivity with any of these three lectins.

The hydrogen fluoride treated core protein was separated by electrophoresis through NaDodSO₄/polyacrylamide gels (10%) and silver stained. Silver staining revealed that the predominant component of the partially stripped mucin was a high molecular weight band of about 400 kd, although faint bands of lower molecular weight could also be observed (Fig. 8, lane 1). Since the high molecular weight material showed a somewhat increased mobility in the gel and reacted with the lectin recognising the linkage sugar, it can be assumed that some sugars had been removed. The fully stripped mucin consisted of two bands of about 68 kd and 72 kd (Fig. 8, lane 2).

Antibody reactive proteins produced by MCF-7 cells

The MCF-7 breast cancer cell line expresses large amounts of HMFG-1 and -2 reactive material on its cell surface (14) and was thus judged to be a suitable source of mRNA for a cDNA library. Before proceeding to screen the MCF-7 library with the monoclonal antibodies, they were tested for their ability to precipitate a component from *in vitro* translation products produced from MCF-7 mRNA. Poly (A)⁺ RNA from MCF-7 was prepared and translated *in vitro*.

Proteins from the translation reaction were immunoprecipitated using the monoclonal antibodies HMFG-1, HMFG-2, SM-3 and SM-4 and displayed by polyacrylamide gel electrophoresis and fluorography (Fig. 9). Two proteins of about 68 kd and 92 kd were immunoprecipitated by SM-3 (lane 2) and SM-4 (lane 1). It was also found that HMFG-1 (lane 4) and HMFG-2 (lane 3) immunoprecipitated these proteins; however, no bands in these areas were precipitated by an irrelevant monoclonal antibody to human interferon (lane 5). The fact that HMFG-1 and -2 immunoprecipitated these proteins was an unexpected finding as it was previously thought that these MABs recognize carbohydrate determinants (1). However, we also found that HMFG-1 and -2 react very strongly with the fully stripped, iodinated core protein (20). These results together with the MAB reactions on the β -galactosidase fusion proteins (see below) confirm that the epitopes for HMFG-1 and -2 are, at least in part, protein in nature.

The abundance of the core protein mRNA in total cellular poly (A)⁺ RNA was 4% as estimated by comparing the amount of (³⁵S)methionine present as immunoprecipitated protein to the amount of methionine incorporated into total protein during *in vitro* translation.

Screening of the cDNA library

The λ gt11 cDNA library made from size selected MCF-7 mRNA (see Methods) was screened initially with the polyclonal antiserum made to the mucin core protein which had been stripped of its carbohydrate. Screening of 2×10^6 plaques resulted in 11 positive clones, 7 of which were taken successfully through two further rounds of plaque purification.

To demonstrate that the reactivity of the phage clones with the antibody probes was due to antigenic determinants on the cDNA translation product, β -galactosidase fusion proteins were made from all 7 clones. The proteins were separated by electrophoresis, transferred to nitrocellulose paper and probed with a variety of antibodies to the stripped mucin, including the polyclonal antiserum which was used initially to select the clones and a cocktail of SM-3 and SM-4. In addition, HMFG-1 and HMFG-2, the two monoclonal antibodies which originally detected this differentiation and tumour-associated epithelial mucin (1,14) were tested. All 7 clones yielded fusion proteins which were specifically recognized by the polyclonal antiserum, the monoclonal cocktail, and HMFG-2. HMFG-1 antibody reacted with 6 of the 7 fusion proteins and failed to recognize the protein from clone 9 which contains the smallest insert. In every case the strongest signal was given by the HMFG-2 antibody and this reaction is shown in Figure 10. Monoclonal antibodies to keratins and to a carbohydrate epitope on this fully glycosylated mucin were used as controls and showed no reactivity. A monoclonal antibody to β -galactosidase was a positive control and the band recognized correlated in every case with the band recognized by the specific antibodies. The sizes of the fusion proteins varied in proportion to the sizes of the cDNA inserts found in the bacteriophage.

Characterization of cDNAs and RNA blot analysis

The inserts from the λ clones were designated pMUC3-10 (omitting pMUC5) and were subcloned into the vector pUC 8 for easier manipulation. The 7 clones were compared to each other for sequence homology. Each of the plasmids was digested with EcoRI and the insert separated on a 1.4% agarose gel. The largest cDNA insert from pMUC10 was used to probe the inserts and found to hybridize to all 6 inserts (Fig.11). pMUC 7 was found to contain two inserts following digestion with EcoRI; however, only 1 of the inserts hybridized to the pMUC10 probe. The insert bands were not derived from phage DNA since the pMUC10 probe did not hybridize to Hind III-digested λ phage DNA.

As shown by agarose gel electrophoresis (Fig. 11), the inserts vary in size from about 200 to up to about 1800 bp. The largest insert from pMUC10 has been used as the hybridization probe in all subsequent experiments.

Because the λ MUC clones were identified only by antibody binding, we needed additional assurance that they were indeed coding for the breast epithelial mucin. To determine the authenticity of pMUC10, we correlated the presence of mRNA hybridizing to the clone with mucin expression in various cell lines. As shown in figure 12, the cDNA hybridized to two transcripts of 4.7 kb and 6.4 kb in the RNA from the breast cancer cell lines MCF-7 and T47D which were shown previously to express the HMFG-2 antigen (1,14). Significantly, the pMUC10 probe hybridized to transcripts of approximately the same size in RNA extracted from normal mammary epithelial cells cultured from milk (42). A third band of 5.7kb can be seen in the RNA from these normal cells. In contrast, three human cell types that lack the mucin, breast fibroblasts, Daudi cells and HS578T, a carcinosarcoma line derived from breast tissue (43), showed no detectable pMUC10-related mRNA. The 6.4 kb band appears to be the most abundantly expressed. The presence of at least two sizes of mRNA from MCF-7 cells correlates with the immunoprecipitation of two proteins of (molecular weights 68 kd and 92 kd) from *in vitro* translated mRNA from MCF-7 cells. The normal mammary epithelial cells were derived from pooled milk samples and the additional transcript observed may be due to polymorphisms among individuals.

Genomic DNA blot hybridization and detection of a restriction fragment length polymorphism (RFLP)

Genomic DNA was prepared from a panel of ten individuals consisting of six unrelated individuals and a family of four, and from three cell lines. The DNAs which were digested with *Hinf*I or *Eco*RI and blotted and hybridized to the radiolabelled pMUC10 insert, exhibit restriction fragment length polymorphisms. The restriction fragments from the ten individuals and three cell lines are shown in figure 13. The pattern consists of either a single band or a doublet of sizes ranging from 3400bp to 6200bp in the *Hinf*I digest (with the exception of the ZR75-1 DNA in lane 12, figure 13A which shows three bands) or from 8200bp to 9600bp in the *Eco*RI digest (Figure 13B), there appears to be a continuous distribution of the fragment sizes which implies a high *in vivo* instability at the locus. The pattern of fragments observed in the family of four (lanes 1-4) suggests that these fragments are allelic. Preliminary studies of the DNA made from white blood cells of normal, related individuals indicate the existence of a number of independent alleles with an autosomal codominant mode of inheritance. These studies will be the subject of a separate investigation.

Discussion

The cDNA clones described here which were obtained from the MCF-7 λ gt11 library were selected using polyclonal and monoclonal antibodies prepared against a normal cellular product, the milk mucin in its deglycosylated form. This was done because it was easier to obtain large quantities of the mucin for stripping than to prepare similar quantities of immunologically related glycoproteins expressed by breast cancer cells (44). The fact that the antibodies did select for cDNA coding for nonglycosylated core protein molecules in MCF-7 cells, strongly suggests that the glycoproteins in these cells, which were originally detected by their reaction with antibodies to the milk mucin, contain the same core protein as this mucin. This is confirmed by the detection of mRNAs of approximately the same sizes in the normal and malignant cells, using one of the probes isolated from the MCF-7 library. We will therefore refer to the antibody reactive glycoproteins on breast cancer cells as mucins, bearing in mind that their processing may be different resulting in molecules of different molecular weights but with the same core protein as that of the milk mucin.

Seven clones were obtained from the MCF-7 library of which the largest was 1800kb. This clone cross hybridized with the other 6 smaller clones. The β -galactosidase fusion proteins expressed by six of the cross-hybridizing lambda clones were reactive with the polyclonal antiserum directed against the mucin core protein as well as with four well-characterized monoclonal antibodies directed to various epitopes on the stripped core protein, SM-3, SM-4, HMFG-1 and HMFG-2 (14,20). The smallest lambda clone, λ MUC9, produced a β -galactosidase fusion protein which reacted with three of the four monoclonal antibodies and with the polyclonal antiserum.

The surprising result that the extensively characterized HMFG-1 and HMFG-2 monoclonal antibodies reacted strongly with the lambda plaques and the fusion proteins and could immunoprecipitate proteins from *in vitro* translated mRNA provides strong evidence that these clones do indeed code for a portion of the mucin core protein. Although previous evidence such as resistance to fixation, boiling, treatment with dithiothreitol and NaDodSO₄ and the presence of multiple epitopes on the molecule suggested that these were carbohydrate (1), it has now been established that the epitopes of the HMFG-1 and HMFG-2 monoclonal antibodies are definitely protein in nature. Carbohydrate may be required to obtain the strongest binding, either as part of the epitope or by conferring some conformational change on the protein portion, but part of the antigenic determinant must consist of an amino acid sequence. Since these two MAbs are reactive with the fully glycosylated milk mucin as well as the stripped core protein, this data means that the intact molecule contains areas of naked peptide which contribute to the antigenic sites for these two antibodies.

Confirmatory evidence that pMUC10 codes for the mammary mucin core protein is provided by RNA blots. The relative abundance of mRNA in the breast cancer cell lines MCF-7, T47D, ZR-75-1 and in normal mammary epithelial cells corresponds to the antigen expression by these cells as measured by the binding of the HMFG-1 and HMFG-2 monoclonal antibodies. Cell types which are negative for antigen expression such as human fibroblasts, Daudi cells and HS578T, a carcinosarcoma line derived from breast (14), are negative in RNA blot hybridizations. A fortuitous observation made with the ZR-75-1 cells yielded indirect strong evidence that pMUC10 does indeed code for the mucin glycoprotein core protein. This cell line, which routinely expresses large amounts both of mRNA and antigen, yielded one preparation of RNA which was unexpectedly negative by blot hybridization. It was subsequently found that those particular ZR-75-1 cells from which the RNA had been made had lost the expression of the antigen as well at this time (as determined by reaction with HMFG-1 and 2). Different passage numbers of the ZR-75-1 cells were recovered and shown once again to express both antigen and message. The sizes of the messages, 4.7 kb and 6.4 kb, are quite large, since a 68 kd or 92 Kd protein would need only about 3 kb to code for the protein portions. This suggests that a large portion of the mRNA may be untranslated. Efforts are underway to obtain a full-length clone.

Thus, the cDNA clones presented here represent a portion of the gene coding for the human mammary mucin which is expressed by differentiated breast tissue as well as by most breast cancers. The major proteins precipitated from *in vitro* translation products of RNA from MCF-7 cells by antibodies to the milk mucin core protein (68Kd) have an apparent molecular weight of 68Kd and 92Kd. These proteins, produced by the breast cancer cell therefore share

epitopes with the 68Kd core protein of the milk mucin (20). Whether a similar 92Kd protein is also produced by normal mammary epithelial cells, and is truncated or destroyed by HP treatment is not yet clear. MCF-7 cells biosynthetically labelled with ^{14}C amino acids yield upon immunoprecipitation with HMFG-1 and HMFG-2 antibodies, two glycosylated proteins of 320 kd and 430 kd and it is possible that each of these glycoproteins utilizes only one core protein of either 68Kd or 92Kd. Alternatively, each of the glycoproteins could contain both the 92Kd and 68Kd proteins either in different proportions or variably glycosylated. Further screening of the library may yield full length cDNAs coding for both sizes of the immunologically related core proteins. Since there appears to be only a single gene (based on Southern blot data obtained by using a partial cDNA probe), it is probable that the multiple messages arise by alternative RNA splicing and this would explain the fact that they contain common sequences. Although a core protein of 68 kd appears to be small to yield a fully glycosylated molecule of greater than 300 kd which contains 50% carbohydrate, there is evidence that such a structure for mucins is possible. Ovine submaxillary mucin has a reported molecular weight of 1×10^6 daltons (45), yet its protein core consists of 650 amino acids resulting in a molecule of 58 kd (46).

The mucins which are detected with HMFG-1 and HMFG-2 MAbs on immunoblots of tumours and breast cancer cell lines show variations in size from 80 kd to 400 kd in the molecular weights of the tumour mucin molecules (1,47). Using these same antibodies which detect high molecular weight mucins present in normal urine, a polymorphism has indeed been shown to be genetically determined (48). Although the very low molecular weight components are likely to represent precursor forms of the mucin which appears to be incompletely processed in many tumour cells (20), the variations in the higher molecular weight components are likely to be due to this genetic polymorphism. It was unclear, however, whether the structural basis of the polymorphism was due to the genetically determined protein or to the carbohydrate portion of the mucin. The detection of restriction fragment length polymorphisms in the Southern blotting experiments using the mucin probe suggest that the mucin polymorphism occurs at the level of the DNA which codes for the protein. Preliminary sequence data suggest that the basis for this polymorphism is a region of variable tandem repeats present in the protein coding sequences. This structural feature may be responsible for the generation of the many allelic restriction fragments at the mucin locus. We are presently investigating the basis of the mucin polymorphism by a Southern blot survey of DNA from white blood cells of normal, related individuals whose inheritance pattern of urinary mucins has been determined. In addition, we are examining DNA preparations made from the white blood cells and tumours of individual breast cancer patients to determine if there is any discordance between genotype in the paired samples, since tandemly repeated DNA may provide an unstable site where recombination or amplification could occur.

The presence of mucins in the majority of carcinomas and their association with the differentiation of mammary epithelial cells makes it particularly important to identify regions involved in the tissue specific and developmental regulation of the gene. Moreover, the introduction of a functional mucin gene into cells should provide insights into the role of this molecule in breast epithelial differentiation and possibly enable us to identify any alterations in the function or expression of the mucin which are related to malignant transformation in the human breast.

Abbreviations

The abbreviations are as follows: PBS, phosphate-buffered saline; MAb, monoclonal antibody; IPTG, isopropyl β -D-thiogalactoside; bp, base pair(s); Kb, kilobase(s).

TABLE 1

Amino acid composition of the human milk mucin - comparison with PAS-O			
Amino acid	HMFG-1 purified milk mucin	Extensively stripped milk mucin	PAS-O (Shimizu & Yamauchi 1982)
Asp	6.1	7.2	6.4
Thr	9.4	9.7	9.8
Ser	9.1	13.0	13.1
Glx	6.3	9.6	8.3
Pro	14.8	14.4	12.0
Gly	8.1	10.1	12.2
Ala	12.3	11.9	13.0
Cys	Not analysed	Not analysed	0.5
Val	6.0	6.3	5.3
Met	0.5	0.4	0.8
Ile	1.6	1.7	1.9

TABLE 1 (continued)

Amino acid composition of the human milk mucin - comparison with PAS-O			
Amino acid	HMFG-1 purified milk mucin	Extensively stripped milk mucin	PAS-O (Shimizu & Yamauchi 1982)
Leu	4.5	4.8	3.7
Tyr	2.0	0.9	1.6
Phe	2.0	1.6	1.7
His	3.2	2.3	3.8
Lys	2.8	3.3	2.2
Arg	4.0	4.0	3.9

Table 2

Reactivity of the antibodies on intact, partially and totally deglycosylated milk mucin			
Antibody	¹²⁵ I cpm bound		
	Intact molecule	Partially stripped mucin	Totally stripped mucin
5.17	8,524	11,925	5,780
9.13	525	3,000	3,328
SM-3	465	15,414	9,200
SM-4	816	16,750	9,561
HMFG-1	32,000	33,768	9,494
HMFG-2	29,500	29,230	15,832
NS2 medium	397	845	650

The binding of the antibodies to iodinated intact, partially and totally deglycosylated milk mucin was assayed using the protein A plate method as described in Materials and Methods.

Claims

5

10

15

20

25

30

35

40

45

1. A polypeptide recognisable by the monoclonal antibody SM3 secreted by hybridoma HSM3 (ECACC 87010701), said polypeptide comprising at least 5 consecutive amino acid residues in a sequence encoded by the tandem repeat sequence of mRNA corresponding to the human polymorphic epithelial mucin core protein gene, which mRNA is obtainable from the human cancer cell line MCF-7, other than the high molecular weight glycoproteins expressed by normal and malignant human epithelial cells, for use in a method of therapy practised on the human or animal body.
2. A polypeptide according to claim 1 comprising at least 10 consecutive residues in a sequence encoded by the said tandem repeat.
3. A polypeptide according to claim 1 or claim 2 linked to a carrier protein.
4. A polypeptide according to any one of claims 1 to 3 having the full sequence encoded by the tandem repeat sequence of the HPEM gene.
5. A polypeptide according to claim 3 or claim 4, wherein at least one amino acid residue bears a linkage sugar substituent.
6. A polypeptide according to claim 5, wherein the linkage sugar bears an oligosaccharide moiety.
7. A polypeptide according to claim 5 or claim 6, wherein each amino acid bearing a substituent is a serine or threonine and the linkage sugar is N-acetyl galactosamine.
8. A polypeptide according to any one of claims 1 to 7 bearing a detectable label or a therapeutically effective moiety.
9. Use of a polypeptide recognisable by the monoclonal antibody SM3 secreted by hybridoma HSM3 (ECACC 87010701), said polypeptide comprising at least 5 consecutive amino acid residues in a sequence encoded by the tandem repeat sequence of mRNA corresponding to the human polymorphic epithelial mucin core protein gene, which mRNA is obtainable from the human cancer cell line MCF-7, other than the high molecular weight glycoproteins expressed by normal and malignant human epithelial cells, in the production of a medicament for use as an immunogen in a method of cancer therapy practised on the human or animal body.
10. Use of a polypeptide recognisable by the monoclonal antibody SM3 secreted by hybridoma HSM3 (ECACC 87010701), said polypeptide comprising at least 5 consecutive amino acid residues in a sequence encoded by the tandem repeat sequence of mRNA corresponding to the human polymorphic epithelial mucin core protein gene, which mRNA is obtainable from the human cancer cell line MCF-7, other than the high molecular weight glycoproteins expressed by normal and malignant human epithelial cells, in a method of in vitro diagnosis.
11. Use according to claim 9 or claim 10 of a polypeptide as defined in any one of claims 2 to 8.

Patentansprüche

50

55

1. Polypeptid, das durch den monoklonalen Antikörper SM3, der von dem Hybridom HSM3 (ECACC 87010701) sekretiert wird, erkannt werden kann, wobei das Polypeptid wenigstens 5 aufeinanderfolgende Aminosäurereste in einer Sequenz umfaßt, die von der Tandem-Wiederholungssequenz der mRNA codiert wird, die dem humanen polymorphen epithelialen Mucin-Core-Proteinen entspricht, wobei die mRNA von der humanen Krebszelllinie MCF-7 erhalten werden kann, wobei das Polypeptid anders ist als die Glykoproteine mit hohem Molekulargewicht, die von normalen und malignen humanen epithelialen Zellen exprimiert werden, zur Verwendung in einem Therapieverfahren, das am menschlichen oder tierischen Körper angewandt wird.
2. Polypeptid nach Anspruch 1, umfassend wenigstens 10 aufeinanderfolgende Reste in einer Sequenz, die von der Tandem-Wiederholung codiert wird.

3. Polypeptid nach Anspruch 1 oder Anspruch 2, das an ein Trägerprotein gebunden ist.
4. Polypeptid nach einem der Ansprüche 1 bis 3, das die vollständige Sequenz, die von der Tandem-Wiederholungssequenz des HPEM-Gens codiert wird, besitzt.
5. Polypeptid nach Anspruch 3 oder Anspruch 4, dadurch **gekennzeichnet**, daß wenigstens ein Aminosäurerest einen Bindungszuckersubstituenten trägt.
6. Polypeptid nach Anspruch 5, dadurch **gekennzeichnet**, daß der Bindungszucker einen Oligosaccharidteil trägt.
7. Polypeptid nach Anspruch 5 oder Anspruch 6, dadurch **gekennzeichnet**, daß jede Aminosäure, die einen Substituenten trägt, ein Serin oder Threonin ist und daß der Bindungszucker N-Acetylgalactosamin ist.
8. Polypeptid nach einem der Ansprüche 1 bis 7, welches eine nachweisbare Markierung oder einen therapeutisch wirksamen Teil trägt.
9. Verwendung eines Polypeptides, das von dem monoklonalen Antikörper SM3, der von dem Hybridom HSM3 (ECACC 87010701) sekretiert wird, erkennbar ist, wobei das Polypeptid wenigstens 5 aufeinanderfolgende Aminosäurereste in einer Sequenz umfaßt, die von der Tandem-Wiederholungssequenz der mRNA codiert wird, die dem humanen polymorphen epithelialen Mucin-Core-Proteinen entspricht, wobei die mRNA von der humanen Krebszelllinie MCF-7 erhalten werden kann, wobei das Polypeptid anders ist als die Glykoproteine mit hohem Molekulargewicht, die von normalen und malignen humanen epithelialen Zellen exprimiert werden, zur Herstellung eines Medikamentes zur Verwendung als ein Immunogen in einem Verfahren der Krebstherapie, welches am menschlichen oder tierischen Körper durchgeführt wird.
10. Verwendung eines Polypeptides, das von dem monoklonalen Antikörper SM3, der von dem Hybridom HSM3 (ECACC 87010701) sekretiert wird, erkennbar ist, wobei das Polypeptid wenigstens 5 aufeinanderfolgende Aminosäurereste in einer Sequenz umfaßt, die von der Tandem-Wiederholungssequenz der mRNA codiert wird, die dem humanen polymorphen epithelialen Mucin-Core-Proteinen entspricht, wobei die mRNA von der humanen Krebszelllinie MCF-7 erhalten werden kann, wobei das Polypeptid anders ist als die Glykoproteine mit hohem Molekulargewicht, die von normalen und malignen humanen epithelialen Zellen exprimiert werden, in einem Verfahren zur in vitro-Diagnose.
11. Verwendung eines wie in einem der Ansprüche 2 bis 8 definierten Polypeptids nach Anspruch 9 oder Anspruch 10.

Revendications

1. Un polypeptide reconnaissable par l'anticorps monoclonal SM3 sécrété par l'hybridome HSM3 (ECACC 87010701), ledit polypeptide comprenant au moins 5 résidus d'acides aminés consécutifs dans une séquence codée par la séquence répétée en tandem de l'ARNm correspondant au gène de la protéine de cors de la mucine épithéliale polymorphe humaine, lequel ARNm peut être obtenu à partir de la lignée de cellules cancéreuses humaines MCF-7, autre que les glycoprotéines de haut poids moléculaire exprimées par des cellules épithéliales humaines normales et malignes, pour utilisation dans une méthode thérapeutique pratiquée sur le corps humain ou animal.
2. Un polypeptide selon la revendication 1, comprenant au moins 10 résidus consécutifs dans une séquence codée par ladite séquence répétée en tandem.
3. Un polypeptide selon la revendication 1 ou la revendication 2, lié à une protéine support.
4. Un polypeptide selon l'une quelconque des revendications 1 à 3, ayant la séquence complète codée par la séquence répétée en tandem du gène HPEM.
5. Un polypeptide selon la revendication 3 ou la revendication 4, dans lequel au moins un résidu d'acide aminé porte un substituant sucre de liaison.
6. Un polypeptide selon la revendication 5, dans lequel le sucre de liaison porte un groupe oligosaccharidique.

7. Un polypeptide selon la revendication 5 ou la revendication 6, dans lequel chaque acide aminé portant un substituant est une sérine ou une thréonine et le sucre de liaison est la N-acétyl galactosamine.
8. Un polypeptide selon l'une quelconque des revendications 1 à 7, portant un marqueur détectable ou un groupe à effet thérapeutique.
9. Utilisation d'un polypeptide reconnaissable par l'anticorps monoclonal SM3 sécrété par l'hybridome HSM3 (ECACC 87010701), ledit polypeptide comprenant au moins 5 résidus d'acides aminés consécutifs dans une séquence codée par la séquence répétée en tandem de l'ARNm correspondant au gène de la protéine de cors de la mucine épithéliale polymorphe humaine, lequel ARNm peut être obtenu à partir de la lignée de cellules cancéreuses humaines MCF-7, autre que les glycoprotéines de haut poids moléculaire exprimées par des cellules épithéliales humaines normales et malignes, dans la production d'un médicament pour utilisation comme immunogène dans une méthode de thérapie du cancer pratiquée sur le corps humain ou animal.
10. Utilisation d'un polypeptide reconnaissable par l'anticorps monoclonal SM3 sécrété par l'hybridome HSM3 (ECACC 87010701), ledit polypeptide comprenant au moins 5 résidus d'acides aminés consécutifs dans une séquence codée par la séquence répétée en tandem de l'ARNm correspondant au gène de la protéine de cors de la mucine épithéliale polymorphe humaine, lequel ARNm peut être obtenu à partir de la lignée de cellules cancéreuses humaines MCF-7, autre que les glycoprotéines de haut poids moléculaire exprimées par des cellules épithéliales humaines normales et malignes, dans une méthode de diagnostic in vitro.
11. Utilisation selon la revendication 9 ou la revendication 10 d'un polypeptide tel que défini dans l'une quelconque des revendications 2 à 8.
